

Project Overview

The proposed project is part of the Citywide effort to substantially reduce the frequency of raw sewage overflows from the City's combined storm/sanitary sewer system to the Spokane River in compliance with an agreement between the City and the Dept. of Ecology.

The proposed underground tanks store combined storm/sanitary flows during significant precipitation events during which time sewer mains are over capacity. Following the precipitation event, stored flows are gradually released back into the sewer mains and transported to the wastewater treatment plant for treatment.

The proposed tanks include odor control equipment.
